Imaging, in particular Computed Tomography (CT) and Magnetic Resonance Imaging (MRI), can be helpful to distinguish movement disorders from other serious conditions that may have similar symptoms. For example, normal pressure hydrocephalus is a condition in which clear fluid surrounding the brain and spinal cord is blocked, causing the ventricles of the brain to fill up with cerebrospinal fluid.

Positron emission tomography (PET) has revealed key insights into the pathophysiology of movement disorders. This paper will focus on how PET investigations of pathophysiology are particularly relevant to Parkinson disease (PD), a neurodegenerative condition usually starting later in life marked by a varying combination of motor and non-motor deficits.

PET Imaging in Movement Disorders

Core tip: By evaluating changes in regional brain perfusion, glucose metabolism and neurotransmitter systems, molecular imaging has shed light onto the etiology, pathophysiology, diagnosis, progression and therapeutic options of movement disorders, including the identification and individualization of potential neuromodulation targets. Continuing progress in the design of positron emission tomography and single photon emission computerized tomography systems, such as new detector materials ...
