In the forest, disturbances are an integral part of the system, to bring in new life. In a mature forest, the taller trees absorb nearly all the sunlight, so the forest floor is permanently shaded. Nothing new can grow until something happens, perhaps a lightning strike, or a flash flood, and then one tree falls or drops branches.

Directional Pruning Directional pruning is an alternative to topping that leaves trees healthier and ultimately reduces line clearing costs. In directional pruning, also called natural pruning or the "Shigo method" (after a well-known tree researcher), only branches that head toward the utility lines (or other obstructions) are pruned.

2.2. Random Forest Learning Since its introduction by Breiman [16], random forest ma chine learning has become very popular due in part to its speed of convergence and generalizability, with a number of tools implementing variations [19]. Inspired by the decision tree algorithm in machine learning, a novel causal network reconstruction framework is proposed with the name Importance Causal Analysis (ICA). The ICA framework is designed in a network level and fills the gap between traditional mutual causality detection methods and the reconstruction of causal networks.

Most other birds in the same forest can only eat small seeds. Ecologist Mauro Galetti and his colleagues measured the seed sizes of palms in forest fragments with and without toucans. The graphs show two of the forest populations they studied. Do these data illustrate directional, stabilizing, disruptive, or balancing selection?

In order to recognize the instantaneous changes of facial microexpressions in natural environment, a method based on optical flow direction histogram and depth multiview network to enhance forest microexpression recognition was proposed. In the preprocessing stage, the histogram equalization of the acquired face image is performed, and then the dense key points of the face are detected.

Directional Selection. When the environment changes, populations will often undergo directional selection (Figure), which selects for phenotypes at one end of the spectrum of existing variation. A classic example of this type of selection is the evolution of the peppered moth in eighteenth- and nineteenth-century England.
